

Outline

Translating with Quantifiers

From English to \forall and \exists

William Starr

10.25.11

- ① Semantics for \forall and \exists
- ② The Aristotelian Forms
- ③ Complex Quantifier Phrases

Satisfaction

The Basic Idea

- Truth tables don't allow us to analyze the meaning of quantifiers
- Instead, we used Tarski's idea of **satisfaction**
- Here's the intuition behind satisfaction
 - $\text{Cube}(x)$ is neither true nor false, we can think of it being **true of an object** o
 - Tarski: satisfaction is being true of an object

Example o satisfies $\text{Small}(x) \wedge \text{Cube}(x)$ if and only if o is a small cube

Satisfaction

The Precise Definition

Definition of Satisfaction

An object o satisfies a wff $S(x)$ containing x as its only **free variable** iff the following two conditions are met:

- ① If we give a o a name that's not in use, call it n_i , then $S(n_i)$ is true
- ② $S(n_i)$ is the result of replacing **every** occurrence of x in $S(x)$ with n_i

- Let's work through a quick example in Tarski's World

Existential Statements

When are They True?

The Point of Satisfaction

- Why do we care about satisfaction?
- Because it allows us to state the truth-conditions of quantified sentences!
- *Something is strange* is true if and only if there is some object o and o is strange
- Truth of $\exists x \text{Strange}(x)$ determined similarly:
 - $\exists x \text{Strange}(x)$ is true if and only if **some** object o **satisfies** $\text{Strange}(x)$
 - How do we figure out whether o satisfies $\text{Strange}(x)$?
 - Give o an unused name n , check whether $\text{Strange}(n)$ comes out true

Existential Statements

Official Semantics

Semantics for \exists

$\exists x S(x)$ is true if and only if there is at least one object that **satisfies** $S(x)$

Example

When is $\exists x (\text{Large}(x) \wedge \text{Tet}(x))$ true?

- By the semantics for \exists :
 - (1) If there is at least one object that **satisfies** $\text{Large}(x) \wedge \text{Tet}(x)$
- By the definition of **satisfaction** (1) amounts to:
 - If when we give o some unused name n , $\text{Large}(n) \wedge \text{Tet}(n)$ comes out true

Existential Statements

The Game Rule for \exists

Game Rule for \exists

Given $\exists x S(x)$:

YOUR COMMITMENT	PLAYER TO MOVE	GOAL
TRUE	you	Choose some o that satisfies
FALSE	Tarski's World	$S(x)$

- $S(x)$ is any wff containing a free occurrence of x :
 - $\text{Cube}(x)$
 - $\text{Cube}(x) \wedge \exists y \text{Small}(y)$
 - $\neg(\forall y \text{Tet}(y) \rightarrow (\text{Small}(x) \vee \text{Cube}(a)))$
- Let's play some games in Tarski's World!

Universal Statements

When are They True?

- *Everything is on fire* is true if and only if for every object o , o is on fire
- Truth of $\forall x \text{OnFire}(x)$ determined similarly:
 - Consider whether every object o in the domain of discourse **satisfies** $\text{OnFire}(x)$
 - That is, for every object o see whether when you give it an unused name n , $\text{OnFire}(n)$ comes out true
 - If so, then $\forall x \text{OnFire}(x)$ is true
 - Otherwise, it is false
- Okay, let's see that precise definition

Universal Statements

Official Semantics

Semantics for \forall

$\forall x S(x)$ is true if and only if every object satisfies $S(x)$

Example

When is $\forall x (\text{Cube}(x) \wedge \text{Small}(x))$ true?

- By the semantics for \forall :
 - (2) Iff every object o satisfies $\text{Cube}(x) \wedge \text{Small}(x)$
- By the definition of **satisfaction** (2) amounts to:
 - Iff when we give each o some unused name n , $\text{Cube}(n) \wedge \text{Small}(n)$ comes out true
- Let's go to Tarski's World

Universal Statements

The Game Rule for \forall

Game Rule for \forall

Given $\forall x S(x)$:

YOUR COMMITMENT	PLAYER TO MOVE	GOAL
TRUE	Tarski's World	Choose some o that does not satisfy $S(x)$
FALSE	you	

- $S(x)$ is **any** wff containing a free occurrence of x
- Let's play some games in Tarski's World

Semantics for the Quantifiers

Summary

- We have learn two methods for understanding the meaning of \forall and \exists :
 - ① Our **satisfaction**-based definition of when $\forall S(x)$ and $\exists x S(x)$ are true
 - ② Our **game**-rule definition, which says how committing to the truth or falsity of a quantified formula affects a game based on that formula
- We just saw the deep parallel in these two methods
- The game just carries you through the steps you'd go through if you applied the semantics for \forall or \exists and then the definition of satisfaction

The Four Aristotelian Forms

What they Are

The Four Aristotelian Forms

- ① *All A's are B's*
- ② *Some A's are B's*
- ③ *No A's are B's*
- ④ *Some A's are not B's*

- These are four of the most common quantificational sentences used in quantificational reasoning
- We can represent all of them in FOL now that we have \forall and \exists
- Today, we'll learn how

The First Aristotelian Form

All A's are B's

The Form: *All A's are B's*

(3) *All rabbits are vicious*

Paraphrase For every x , if x is a rabbit then x is vicious

Translation $\forall x (\text{Rabbit}(x) \rightarrow \text{Vicious}(x))$

- This translation has the **form**: $\forall x (A(x) \rightarrow B(x))$

General Fact

All A's are B's translates as $\forall x (A(x) \rightarrow B(x))$

The Second Aristotelian Form

Some A's are B's

The Form: *Some A's are B's*

(4) *Some professors are vicious*

Paraphrase Some thing x is both a professor and vicious

Translation $\exists x (\text{Professor}(x) \wedge \text{Vicious}(x))$

- This translation has the **form**: $\exists x (A(x) \wedge B(x))$

General Fact

Some A's are B's translates as $\exists x (A(x) \wedge B(x))$

The Second Aristotelian Form

Comments

- We've learned two facts:
 - All As are Bs* translates as $\forall x (A(x) \rightarrow B(x))$
 - Some As are Bs* translates as $\exists x (A(x) \wedge B(x))$
- Why do we use \rightarrow in one case, and \wedge in the other?
- Why don't we translate *Some As are Bs* as $\exists x (A(x) \rightarrow B(x))$?
- We'll see this by doing exercise 9.8

The Third Aristotelian Form

No A's are B's

The Form: *No A's are B's*

(5) *No students are drunk*

Paraphrase 1 For every x , if x is a student then x is **not** drunk

Paraphrase 2 It is not the case that for some x , x is a student and x is drunk

Translation 1 $\forall x (\text{Student}(x) \rightarrow \neg \text{Drunk}(x))$

Translation 2 $\neg \exists x (\text{Student}(x) \wedge \text{Drunk}(x))$

- Translation 1 has the **form**: $\forall x (A(x) \rightarrow \neg B(x))$
- Translation 2 has the **form**: $\neg \exists x (A(x) \wedge B(x))$
- These are **equivalent**, and we'll eventually prove it

The Third Aristotelian Form

No A's are B's (Continued)

General Fact

No A's are B's translates as:

$$\forall x (A(x) \rightarrow \neg B(x))$$

Or:

$$\neg \exists x (A(x) \wedge B(x))$$

The Fourth Aristotelian Form

Some A's are not B's

The Form: *Some A's are not B's*

(6) *Some excuses are not believable*

Paraphrase For some x , x is an excuse and x is not believable

Translation $\exists x (\text{Excuse}(x) \wedge \neg \text{Believable}(x))$

- This translation has the **form**: $\exists x (A(x) \wedge \neg B(x))$

General Fact

Some A's are not B's translates as $\exists x (A(x) \wedge \neg B(x))$

The 4 Aristotelian Forms

Summary

The Aristotelian Forms and Their Translations

<i>All A's are B's</i>	$\forall x (A(x) \rightarrow B(x))$
<i>Some A's are B's</i>	$\exists x (A(x) \wedge B(x))$
<i>No A's are B's</i>	$\forall x (A(x) \rightarrow \neg B(x))$
<i>Some A's are not B's</i>	$\exists x (A(x) \wedge \neg B(x))$

In-Class Exercise

Translation!

- (7) All cars are vehicles
 - $\forall x (\text{Cars}(x) \rightarrow \text{Vehicle}(x))$
- (8) Some vehicles are expensive
 - $\exists x (\text{Vehicles}(x) \wedge \text{Expensive}(x))$
- (9) No vehicles are students
 - $\forall x (\text{Vehicle}(x) \rightarrow \neg \text{Student}(x))$
- (10) Some students are not vehicles
 - $\exists x (\text{Students}(x) \wedge \neg \text{Vehicles}(x))$

Beyond the Second Form

What to Do

- Translate:
(11) *Some cubes are in front of c*
- It has the second form: *Some A's are B's*. So:

$$\exists x (\text{Cube}(x) \wedge \text{FrontOf}(x, b))$$

- What about:
(12) *Some small cubes are in front of c*
That's not one of the forms we know!
- Still, it's pretty obvious how it should go:

$$\exists x (\text{Small}(x) \wedge \text{Cube}(x) \wedge \text{FrontOf}(x, b))$$

Beyond the Second Form

Multiply Restricted Existentials

- From the second form, we know that you **restrict \exists with \wedge**
 - An existential quantifier multiply restricted means multiple conjuncts restricting \exists :
- (13) *Some cute little kitten ate Alex*
- $$\exists x (\text{Cute}(x) \wedge \text{Little}(x) \wedge \text{Kitten}(x) \wedge \text{Ate}(x, \text{alex}))$$
- (14) *A small rat scared Jay*
- $$\exists x (\text{Small}(x) \wedge \text{Rat}(x) \wedge \text{Scared}(x, \text{jay}))$$
- (15) *At least one small cube in front of b is left of c*
- $$\exists x (\text{Small}(x) \wedge \text{Cube}(x) \wedge \text{FrontOf}(x, b) \wedge \text{LeftOf}(x, c))$$

Beyond the First Form

What to Do?

- Translate:
(16) *All cubes are in front of c*
- It's form is *All A's are B's*, so:

$$\forall x (\text{Cube}(x) \rightarrow \text{FrontOf}(x, b))$$

- What about:
(17) *All small cubes are in front of c*
- That's not one of the forms we know!

Beyond the First Form

What to Do

- We know that you **restrict \forall with \rightarrow** (1st Form)
 - A universal quantifier multiply restricted means multiple restrictions of \forall with \rightarrow :
- (18) *All cute little kittens hate Alex*
- $$\forall x (\text{Cute}(x) \rightarrow (\text{Little}(x) \rightarrow (\text{Kitten}(x) \rightarrow \text{Hate}(x, \text{alex}))))$$
- (19) *Every small rat scared Jay*
- $$\forall x (\text{Small}(x) \rightarrow (\text{Rat}(x) \rightarrow \text{Scared}(x, \text{jay})))$$
- (20) *Every small cube in front of b is left of c*
- $$\forall x (\text{Small}(x) \rightarrow (\text{Cube}(x) \rightarrow (\text{FrontOf}(x, b) \rightarrow \text{LeftOf}(x, c))))$$

Beyond the First Form

Using \wedge Instead of \rightarrow

- Instead of nesting \rightarrow , you can use conjoin the restrictions into one:

$$\forall x (\text{Cute}(x) \rightarrow (\text{Little}(x) \rightarrow (\text{Kitten}(x) \rightarrow \text{Hate}(x, \text{alex}))))$$

Is Equivalent to:

$$\forall x ((\text{Cute}(x) \wedge \text{Little}(x) \wedge \text{Kitten}(x)) \rightarrow \text{Hate}(x, \text{alex}))$$

- This is because of the following general equivalence:

$$A \rightarrow (B \rightarrow C) \iff (A \wedge B) \rightarrow C$$

Subjects and Objects

Some Terminology

- Some predicates like *love* relate two things:
(21) *Kay loves Jay*
- When you have a predicate that relates two things, it's helpful to have some terminology to distinguish those two things
- *Kay* is the **subject**
- *Jay* is the **object**
- Intuitively, the subject is what the sentence is primarily about

Roaming Quantifiers

In Object Position

- So far, we've only considered sentences with quantifiers in subject-position:
(22) *Every cube is in front of **b***
- What about when you have a quantifier in object-position?
(23) ***b** is in front of **everything***
- Just stick \forall out in front of the predicate, and 'quantify into' the object position

$$\forall x \text{FrontOf}(b, x)$$

Roaming Quantifiers

More on Object Position

- Okay, but what happens when the quantifier in object position is **restricted**
(24) ***b** is in front of **every cube***
- You have to **move its restrictor** out front **too**:
(24') $\forall x (\text{Cube}(x) \rightarrow \text{FrontOf}(b, x))$
- This holds for **multiply restricted** ones too:
(25) ***b** is in front of **every small cube***
Translates as:
(25') $\forall x ((\text{Cube}(x) \wedge \text{Small}(x)) \rightarrow \text{FrontOf}(b, x))$

Roaming Quantifiers

Some More Examples

(26) shows that you move the restrictors to the left of the predicate, but no further!

(26) a. *It's not the case that **b** is a large cube*

b. $\neg\exists y (\text{Large}(y) \wedge \text{Cube}(y) \wedge \mathbf{b} = y)$

(27) a. *It's not the case that something is a large cube*

b. $\neg\exists y (\text{Large}(y) \wedge \text{Cube}(y) \wedge \exists x x = y)$

(28) a. *Everything between **c** and **b** is **a***

b. $\forall x (\text{Between}(x, \mathbf{c}, \mathbf{b}) \rightarrow x = \mathbf{a})$

(29) a. *Everything between **c** and **b** is a cube*

b. $\forall x (\text{Between}(x, \mathbf{c}, \mathbf{b}) \rightarrow \exists y (\text{Cube}(y) \wedge x = y))$

An Oddity

Existentials in Conditionals

- Consider:

(30) *If a yokel drools, he snores*

- *a* is **existential**, right?

- So, it seems like we should translate (30) as:

(31) $\exists x ((\text{Yokel}(x) \wedge \text{Drools}(x)) \rightarrow \text{Snores}(x))$

- This requires at least one yokel that drools to snore
- Is that strong enough?

An Oddity

Existentials in Conditionals are Universal?

- Most people get the intuition that:

(30) *If a yokel drools, he snores*

Is equivalent to:

(32) *Every yokel who drools snores*

- But then (30) shouldn't be translated with \exists as in (31), but rather:

(33) $\forall x ((\text{Yokel}(x) \wedge \text{Drools}(x)) \rightarrow \text{Snores}(x))$

- So, beware, in conditionals, existentials sound like universals
